SHORT COMMUNICATION

_Hibbertia sejuncta_, a new, rare species from Western Australia, with notes on _H. helianthemoides_

_Hibbertia helianthemoides_ (Turcz.) F.Muell. was described (as _Candollea helianthemoides_ Turcz.) in 1849, based on a specimen collected by James Drummond on his 4th collecting expedition, most likely in the Stirling Range (Drummond’s 4th expedition traversed the Stirling Range (George 2009), and the type specimen closely matches specimens from there). Wheeler (2002), in a revision of a small species group that she regarded included _H. helianthemoides_, accepted it as endemic in the Stirling Range, with the exception of one specimen from near Tenterden, which is outside the Range but close to its western end. Wheeler subsequently determined a number of specimens at PERTH, particularly from the area between Perth and Eneabba, as a ‘northern variant’ of _H. helianthemoides_, although this variant was not provided with a formal phrase name.

A conservation assessment of _H. helianthemoides_ s. str. (i.e. before the inclusion of the ‘northern variant’) led to it being listed as Priority Four under Department of Parks and Wildlife Conservation Codes for Western Australian Flora (Jones 2015). However, under the expanded circumscription including the ‘northern variant’, a conservation rating of ‘Least Concern’ would be warranted. Given uncertainty regarding the taxonomic status of the ‘northern variant’, a review of the species was initiated to help determine its range and conservation status.

After study of all available material of _H. helianthemoides_ at the Western Australian Herbarium, it became clear that: (1) only specimens from the western end of the Stirling Range match the type; (2) all specimens of the ‘northern variant’ can be adequately referred to a number of other taxa including _H. sericosepala_ K.R.Thiele, _H. huegelii_ (Endl.) F.Muell., _H. leucocrossa_ K.R.Thiele and _H. desmophylla_ (Benth.) F.Muell.; (3) five specimens from two widely disjunct localities in the Avon Wheatbelt bioregion (Department of the Environment 2013), from near Tenterden and Lake Muir, comprise a new species described here as _H. sejuncta_ K.R.Thiele & Nge.

_Hibbertia sejuncta_ K.R.Thiele & Nge, _sp. nov._

_Type_: [near Tenterden] Western Australia [precise locality withheld for conservation reasons], 22 August 2016, K.R. Thiele 5353 (holo: PERTH 08813477; iso: AD, CANB).

Low-growing _shrubs_ to 25 cm high, with short, erect branches from prostrate or spreading main stems, resprouting from the rootstock after fire; branchlets moderately crisped-pubescent with white to pale grey, simple, spreading hairs. _Leaves_ crowded, ± fasciculate, linear, (3.5–)8–10(–20) mm long, 0.6–0.8 mm wide; leaf lamina very narrow but distinctly recurved (abaxial surface grooved adjacent to the relatively broad midrib), non-tuberculate, sparsely pilose with spreading, crisped, white to pale grey, simple hairs to c. 1 mm long; apex obtuse. _Flowers_ sessile, mostly single and terminating...
axillary short-shoots; flower-subtending bracts 3–5, brown, scarious, to 1.5 mm long, the upper ones orbicular and glabrous, the lower ones narrower, acute, and with a sparse indumentum as for the leaves. Sepals 5, ovate, 3.5–5.2 mm long, glabrous, thin-textured except for a slightly thicker but not prominent midrib; outer sepals shorter and more acute than the inner, which are obtuse-apiculate. Petals 5, yellow, broadly obovate, 4.0–5.5 mm long, ± entire to deeply emarginate. Stamens 11, all around the gynoecium, in 3 bundles of 3 stamens each fused by their filaments, and with two single stamens; filaments 1.0–1.2 mm long, those of the stamen bundles fused for most of their length except the inner stamen which has a slightly longer free portion; anthers rectangular, 1.2–1.5 mm long, dehiscing by introrse, longitudinal slits. Staminodes absent. Carpels 3; ovaries compressed-globular, glabrous; styles excentrically erect-incurved from the carpel apex, 1.2–1.8 mm long. Ovules 1(2) per carpel. Seeds ± globular, glossy, brown, c. 2 mm diam.; aril pale, deeply divided into finger-like lobes, covering < half the seed.

Diagnostic features. Hibbertia sejuncta may be distinguished from all other Western Australian taxa by its combination of stamens arranged all around the three glabrous carpels, with two free stamens and three bundles of three stamens each, and linear, pilose leaves with the lamina very narrow but distinctly recurved either side of a prominent midrib.

Phenology. Peak flowering is in late winter and early spring, with sporadic flowering at other times of year when conditions are suitable.

Distribution and habitat. Hibbertia sejuncta occurs at two widely disjunct locations, near Tenterden and near Lake Muir. At both sites it occurs in winter-damp areas on gentle slopes adjacent to minor drainage lines and run-on areas, in grey sand beneath low, open jarrah forest.

Conservation status. Hibbertia sejuncta is listed by Jones (2015) as Priority Two under Department of Parks and Wildlife Conservation Codes for Western Australian Flora, under the name H. sp. Tenterden (M. Sowry 154).

Etymology. The epithet is from the Latin sejunctus (disjointed, separated) and refers to the highly disjunct distribution of the new species. While further collections may uncover new populations, the area in which it occurs is well-collected for Hibbertia, and the taxon is likely to remain disjunct and scattered.

Notes. Hibbertia sejuncta belongs in Hibbertia Andrews subgen. Hibbertia, and may be phylogenetically close to H. helianthemoides. Although neither species was included in the only available phylogenetic analysis of the genus (Horn 2005), they are morphologically closely related to species in a well-supported clade comprising H. depressa Steud., H. fitzgeraldensis J.R.Wheeler, H. hibbertioides (Steud.) J.R.Wheeler, H. notibractea J.R.Wheeler, H. rupicola (S.Moore) C.A.Gardner and H. sericosepala (as H. sp. Gnangara). These taxa share an actinomorphic androecium with stamens in five bundles united by their filaments (in some species with two stamens single) surrounding three (rarely five) glabrous, uniovulate carpels.
Hibbertia sejuncta has the narrowest leaves of any species in subgen. Hibbertia, with the recurved lamina scarcely wider than the prominent midrib. In this respect it is similar to many species of subgen. Hemistemma Juss. ex Thouars that have short, ‘ericoid’ leaves with a strongly revolute lamina appressed to the midrib abaxially. Horn (2005) noted that all species in subgen. Hemistemma have leaves with a single vascular trace at base, while leaves in subgen. Hibbertia are 3-traced. Hibbertia sejuncta leaves are 1-traced like those of subgen. Hemistemma, indicating that this character may be partially a reflection of leaf width rather than being phylogenetically informative.

A specimen from near Wickepin initially assigned to H. sp. Tenterden (H.B. Shugg s.n. PERTH 04388348), is superficially similar to H. sejuncta but lacks its distinctive leaves, instead having narrow but flat leaves without a revolute lamina; it also has a more appressed leaf indumentum. It has been tentatively assigned as a significant range extension of H. priceana J.R.Wheeler, to which it is most similar.

Acknowledgements

We thank the Curator and staff of the Western Australian Herbarium for access to specimens, Hazel Green for assistance with an understanding of the history of areas of remnant vegetation around Wickepin, and Barbara Rye for useful comments and edits on the manuscript.
